Summary

In ideal plasma the number of charges Λ_D in the Debye sphere must be large.

Debye length

In a plasma with electron temperature $T_e = 10000 eV$ and electron density $n_e = 10^{14} cm^{-3}$, the number of particles in Debye sphere is 4×10^7 .

- In Hot Dense Plasma: the number of particles in Debye sphere is 4 when $T_{\rm e}=100{\rm eV}$ and $n_{\rm e}=10^{22}{\rm cm}^{-3}$.
- In Warm Dense plasma, the number of charges in Debye sphere might be less than 1.

Note: WDM does not obey the plasma state theories.

Collision frequency

In a simple model where ions are assumed to be immobile, the electron ion collision frequency is given as

$$\nu_{\rm ei} = \frac{8\pi Z^2 e^2 n_{\rm i}}{3^{3/2} m_{\rm e}^{1/2} (K_{\rm B} T_{\rm e})^{3/2}} \ln \Lambda_c$$

Coulomb logarithm

$$\Lambda_c = \frac{(K_{\rm B}T_{\rm e})^{3/2}}{2Ze^2\sqrt{4\pi e^2 n_{\rm i}}}$$

For WDM the collision frequency is negative value.

Conductivity I

From the generalized Ohm's law

$$I = \frac{1}{R} \ V \qquad \vec{J} = \sigma \vec{E}$$

 The current density in an ideal plasma is proportional to the applied electric field.

$$\sigma = \frac{e^2 n_{\rm e}}{m_{\rm e} \nu_{\rm ie}} = \frac{3^{1/2}}{8\pi Z e^2 m_{\rm e}^{1/2}} \frac{(K_{\rm B} T_{\rm e})^{3/2}}{\ln(\Lambda_c)}$$

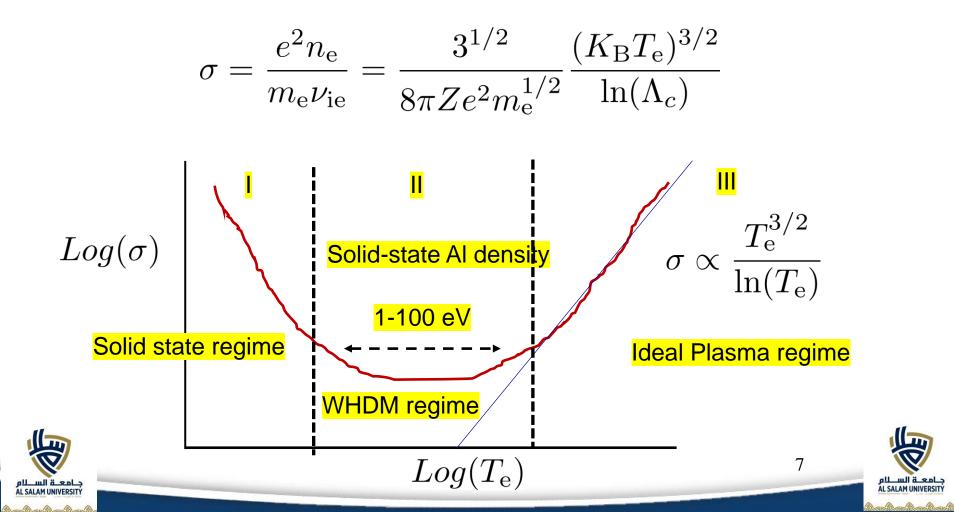

• At constant density:

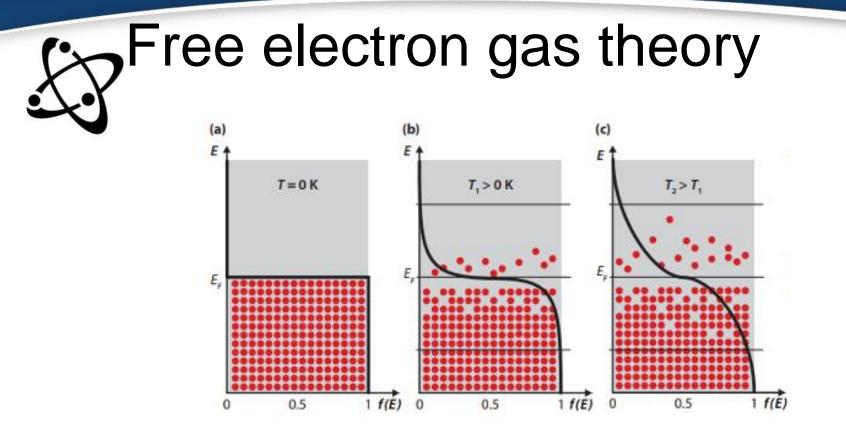

$$\sigma \propto \frac{T_{\rm e}^{3/2}}{\ln(T_{\rm e})}$$

Fermi-Dirac Distribution

$$f(E) = \frac{1}{e^{(E-E_{\rm f})} + 1} \qquad E_{\rm f} = \frac{\hbar^2}{2m} (3\pi^2 n)^{2/3}$$

For solid state density: $E_f \approx 2.2 eV$

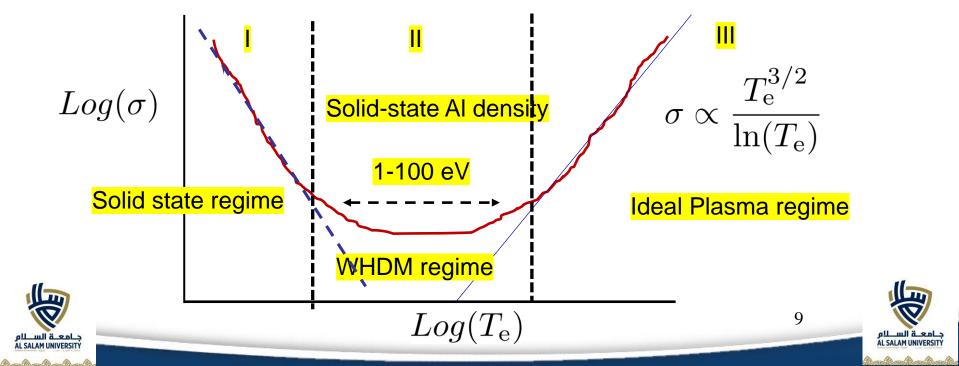

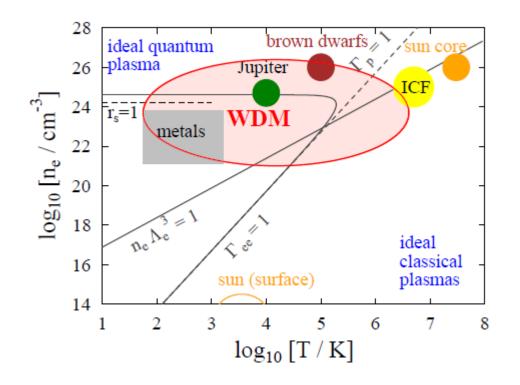

Conductivity III

The conductivity of a metal decreases by increasing the temperature.

$$\sigma = \frac{e^2 n_{\rm e}}{m_{\rm e} \nu_{\rm ie}} \propto \frac{1}{T}$$

Warm Dense Matter

K. Wünsch

- Temperature of few electronvolts
- Solid state density and beyond
- ICF, shock experiments, giant planets, and brown dwarfs
- Theories of solid, condensed matter, or ideal plasma are not valid
- No single theoretical model describes the behavior of WDM
 - Partial ionization
 - Arbitrary degeneracy
 - Strong ionic correlations

Glenzer et al PRL 98 065002(2007)

WDM in Laboratory

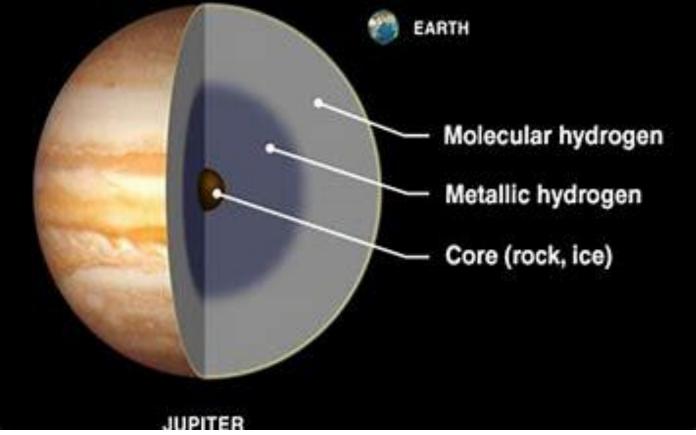

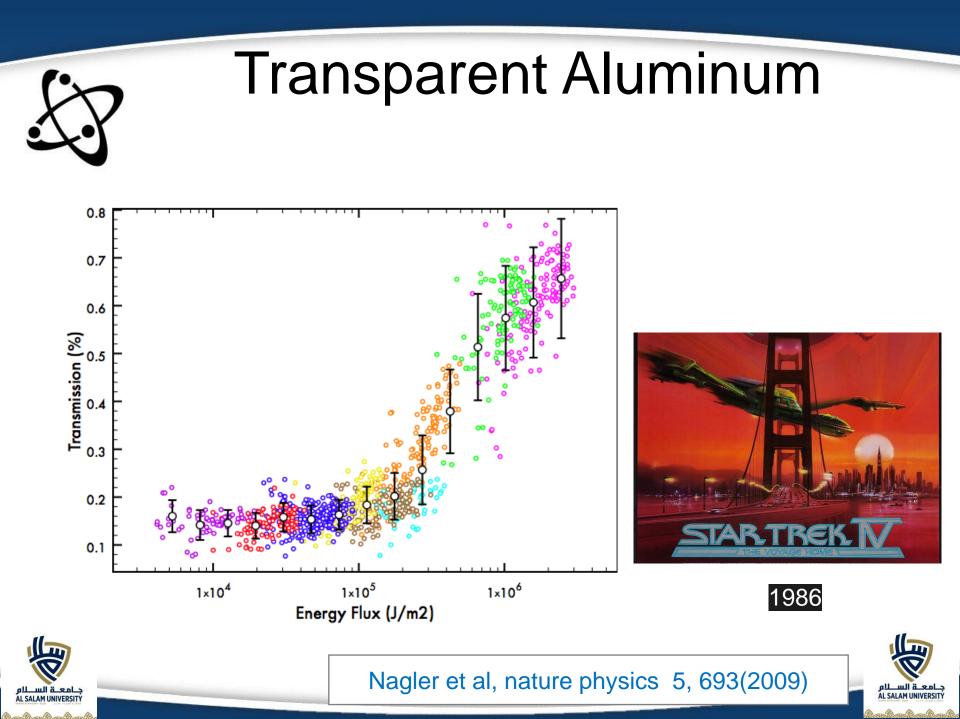

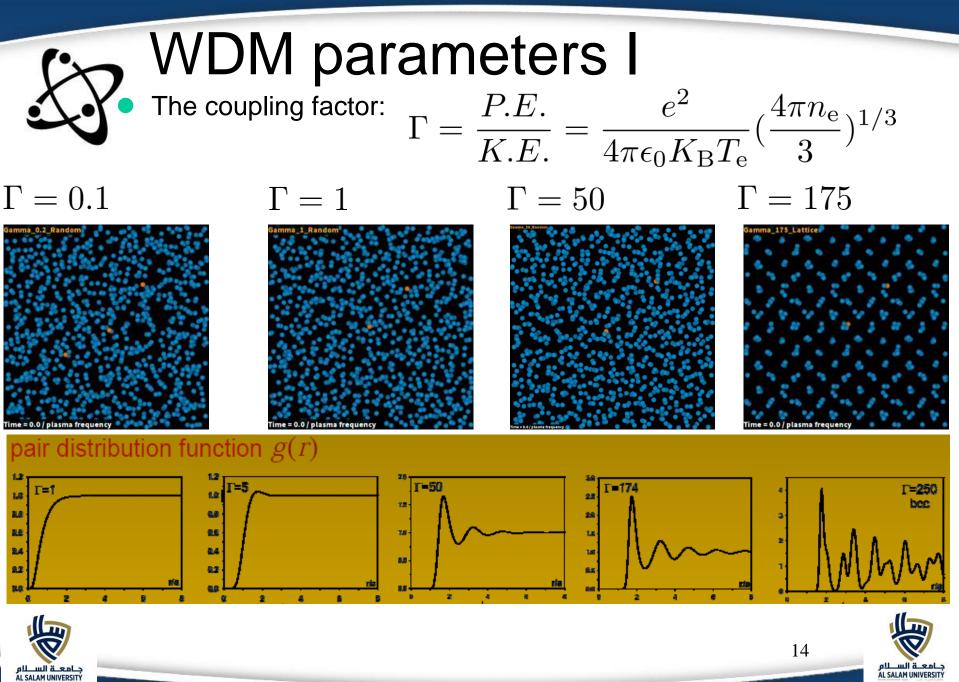

Metallic Hydrogen in Jupiter

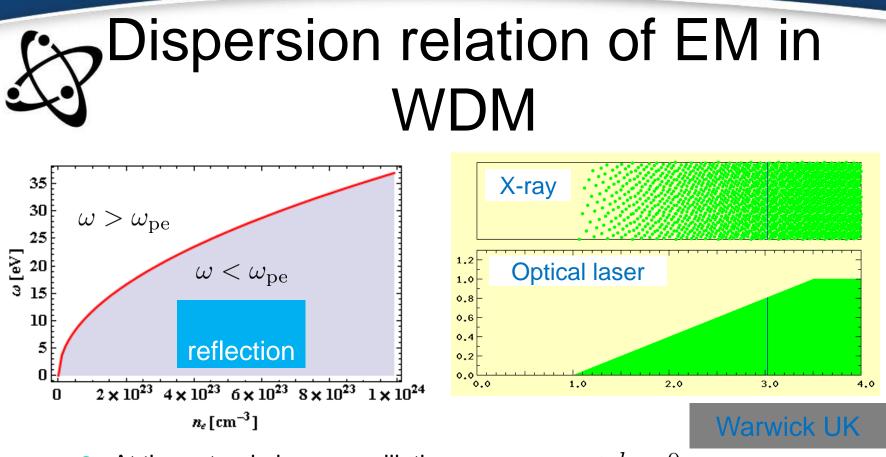

$$\theta_{\rm e} = \frac{K_{\rm B}T_{\rm e}}{E_{\rm f}} = \frac{2m_{\rm e}K_{\rm B}T_{\rm e}}{\hbar^2} (3\pi^2 n_{\rm e})^{-2/3}$$

- When $\theta_{\rm e} < 1$, most electrons populate states in Fermi see. Quantum effects are important.
- The screening length or Debye length must be calculated from Fermi distribution not form Maxwell-Boltzmann distribution like in ideal plasma.

$$\lambda_{\rm D}^{-2} = \frac{e^2 m_{\rm e}^{3/2}}{\sqrt{2}\pi^2 \epsilon_0 \hbar^3} \int dE E^{-1/2} f(E)$$

• At the natural plasma oscillation: $\omega_{
m pe}=\omega
ightarrow k=0$

• At the cut off, the wave is reflected:

WDM is transparent in x-ray regime:

$$\omega_{\rm pe} > \omega \to k = i\kappa$$

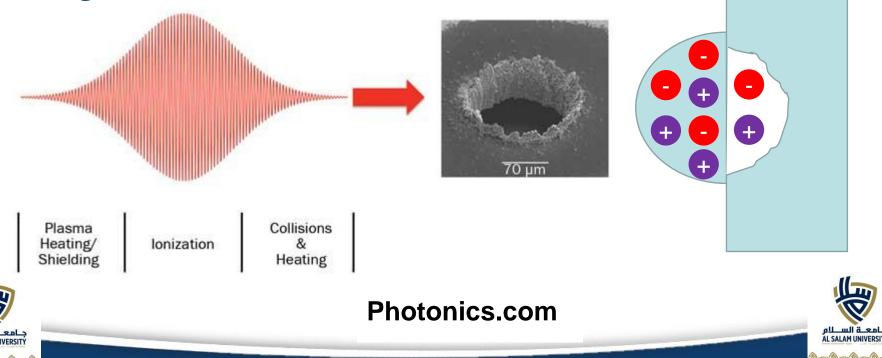

$$n_{\rm e} = 10^{24} {\rm cm}^{-3} \to \lambda \le 33nm$$

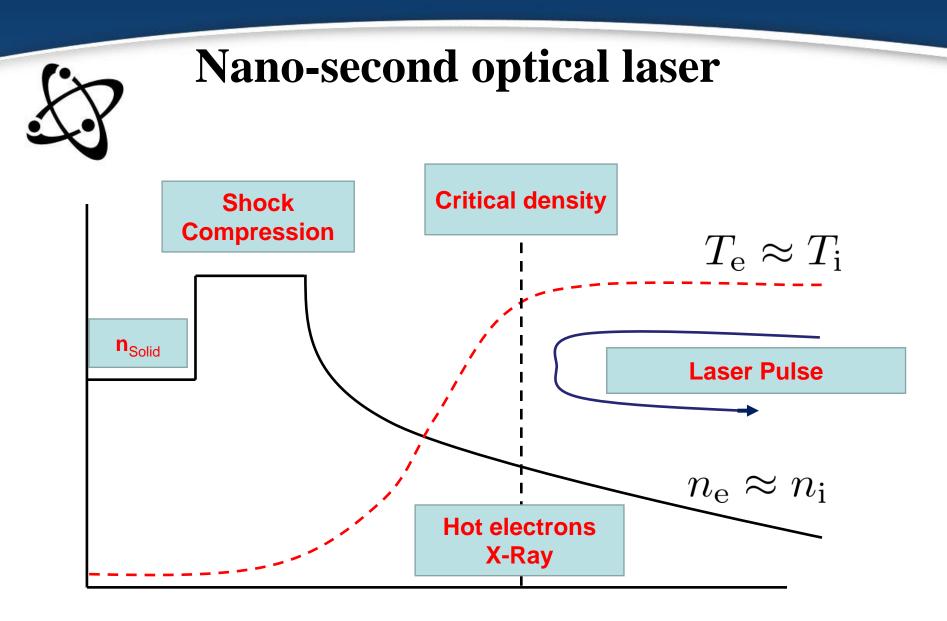

£?

Plasma creation over solid targets

- The first seed of electrons are generated via MPI, Tunnel ionization, or , BSI.
- The free electrons gain energy from the laser electric field, then make further ionization by collision with neutral particles in the target.

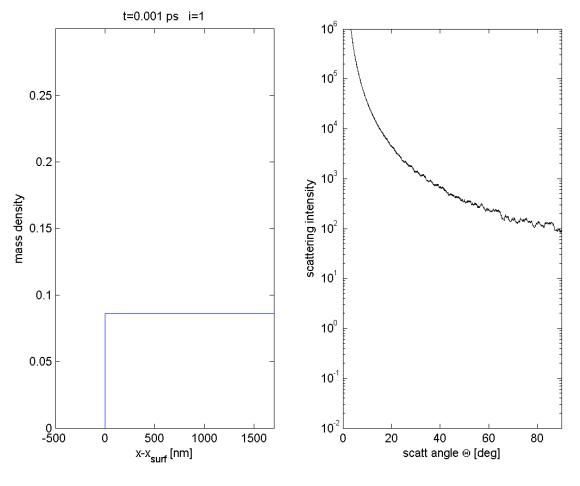

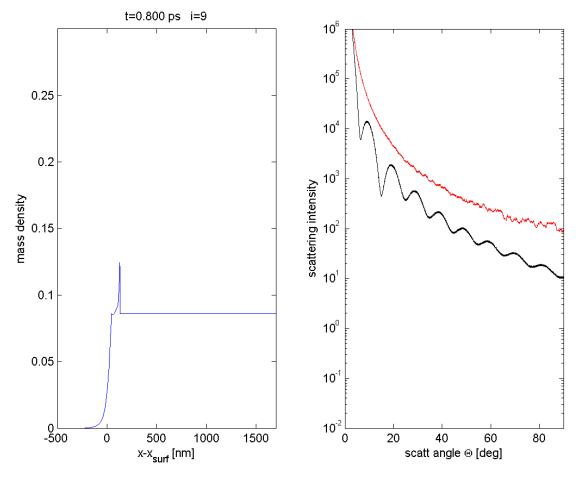

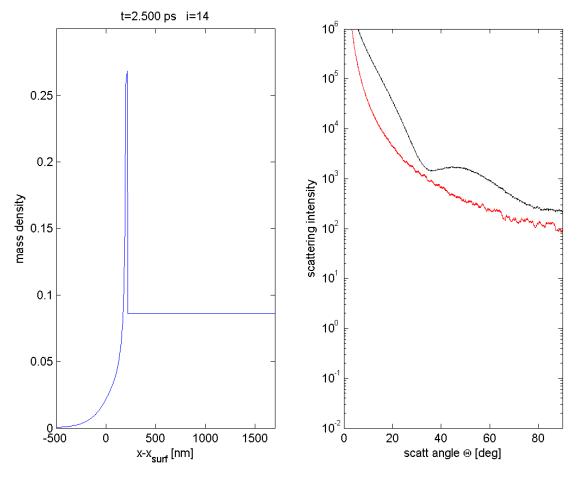

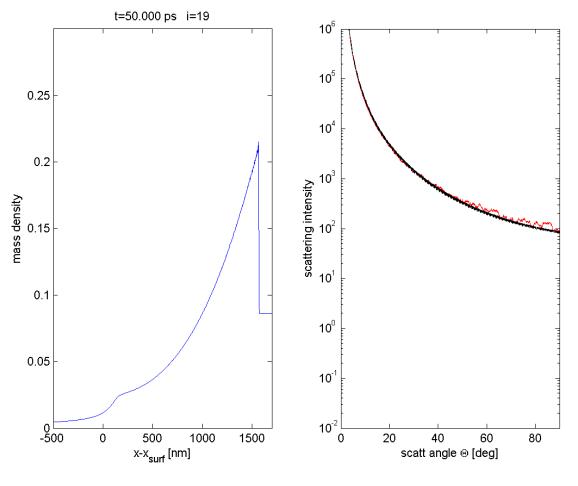

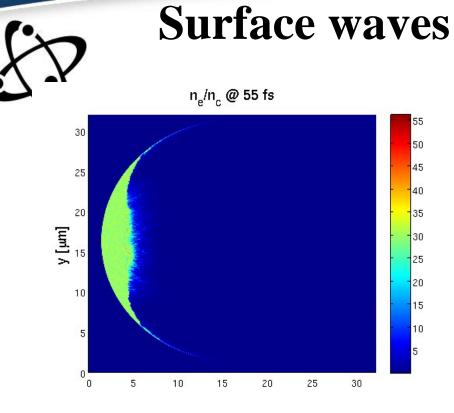

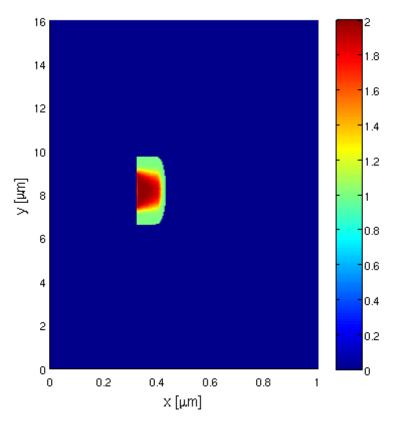

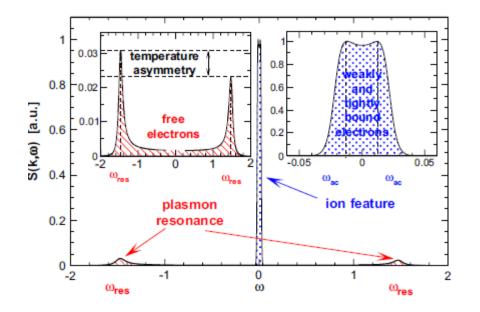

X-ray Thomson scattering

 $N_{\rm e}F_{\rm ee}^{tot} = \langle \rho_{\rm b}(\vec{k},t)\rho_{\rm b}(-\vec{k},t)\rangle + 2\langle \rho_{\rm f}(\vec{k},t)\rho_{\rm b}(-\vec{k},t)\rangle + \langle \rho_{\rm f}(\vec{k},t)\rho_{\rm f}(-\vec{k},t)\rangle$

A. Höll et al., HEDP 3, 120(2007)

- Thomson scattering has two distinct features:
 - Inelastic scattering (frequency shifted) from free electrons and bound free transitions
 - Unshifted Rayleigh peak (elastic) due to electrons comoving with the ions
- The electrons in partially ioized system can be split into bound and free electrons

$$\rho_{\rm e} = \rho_{\rm b} + \rho_{\rm f}$$

Intermediate scattering function

Born-Mermin approximation

• Fluctuation-dissipation theorem :

$$S_{\rm ee}^0(k,\omega) = -\frac{\epsilon_0 \hbar k^2}{\pi e^2 n_{\rm e}} \frac{{\rm Im}\epsilon^{-1}({\bf k},\omega)}{1 - \exp(-\hbar\omega/k_{\rm B}T_{\rm e})}$$

$$\epsilon^{\text{RPA}}(\vec{k},\omega) = 1 - \frac{1}{\epsilon_0 \Omega_0 k^2} \sum_p e^2 \frac{f_{p+k/2}^e - f_{p-k/2}^e}{\Delta E_{p,k}^e - \hbar(i\omega + i\eta)}$$

• Mermin ansatz :

$$\epsilon_M(k,\omega) = 1 + \frac{\left(1 + \frac{i\nu(\omega)}{\omega}\right)\left[\epsilon^{\text{RPA}}(k,\omega + i\nu(\omega)) - 1\right]}{1 + i\frac{\nu(\omega)}{\omega}\frac{\epsilon^{\text{RPA}}(k,\omega + i\nu(\omega)) - 1}{\epsilon^{\text{RPA}}(k,0) - 1}}$$

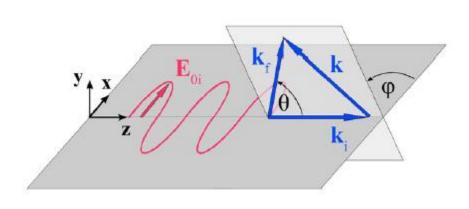

• $\nu(\omega)$ is the dynamic collision frequency via Born approximation.

Glenzer and Redmer, RMP 81, 1625(2009)

Back and forward scattering

 The momentum transfer depends on the scattering angle

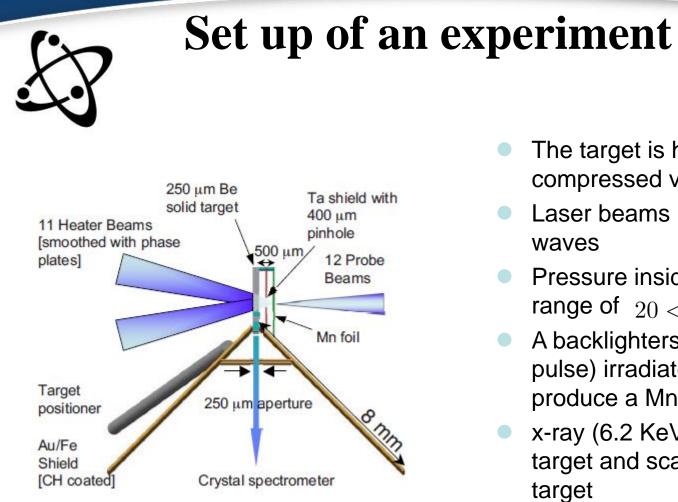

$$k = |k_{\rm f} - k_{\rm i}| = \frac{4\pi}{\lambda_{\rm i}} \sin(\theta/2)$$

- Dimensionless scattering parameter $\alpha = \frac{1}{k\lambda_{\rm sc}} = \frac{l}{2\pi\lambda_{\rm sc}}$
 - *l* is the electron density fluctuation
 - $\lambda_{
 m sc}$ is the screening length
- Collective scattering: ($\alpha > 1$)
 - the scattering reflects the electron density fluctuations
 - Plasmon features
- Non-collective scattering:($\alpha < 1$)
 - the scattering reflects the velocity distribution of electrons
 - Compton features

Glenzer and Redmer, RMP 81, 1625(2009)

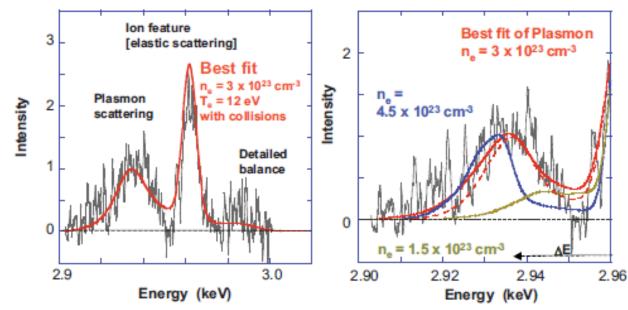

- The target is heated and compressed via laser beams
- Laser beams launch shock
- Pressure inside the target in the range of 20 < P < 35 Mbar
- A backlighters (probe laser pulse) irradiate a Mn target to produce a Mn-He- α line
- x-ray (6.2 KeV) penetrates the target and scattered off the

Free electron laser

✤The free electron laser (FEL) is a device that transforms the kinetic energy of a relativistic electron beam into electromagnetic (EM) radiation.

✦Electrons in an FEL are not

bound to atoms or molecules.

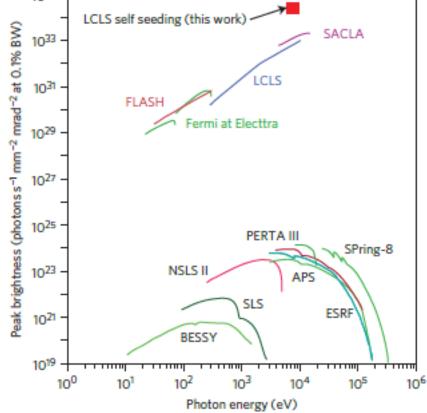

The "free" electrons traverse a series of alternating magnets, called a "wiggler," and radiate light at wavelengths depending on electrons' energy, wiggler period and magnetic field.

Tremendous XFEL intensity

Density Functional Theory

- 1920: Introduction of the Thomas-Fermi model.
- 1964: Hohenberg-Kohn paper proving existence of exact DF.
- 1965: Kohn-Sham scheme introduced.
- 1970 and early 80s: LDA. DFT becomes useful.
- 1985: Incorporation of DFT into molecular dynamics (Car-Parrinello)
 (Now one of PRL's top 10 cited papers).
- 1988: Becke and LYP functionals. DFT useful for some chemistry.
- 1998: Nobel prize awarded to Walter Kohn in chemistry for development of DFT.

Motivation

Have you solved Schrodinger equation for Hydrogen Atom?

$$\begin{split} H\psi(r,\theta,\phi) &= E\psi(r,\theta,\phi) \\ (\frac{-\hbar^2}{2m}\nabla^2 + V(r))\psi(r,\theta,\phi) &= E\psi(r,\theta,\phi) \\ \bullet \qquad \text{K.E.} \qquad \text{P.E.} \\ V(r) &= \frac{-e^2}{4\pi\epsilon_0 r} \end{split}$$

• Is there an exact solution for complex systems?

Hamiltonian of a molecule

In a molecule we have many electrons and many nuclei.

- According to <u>Born-Openheimer</u> approximations: nuclei are very slow and their kinetic motion are negligible.
- The Hamiltonian should contain
 - The kinetic energy of electrons
 - Potential energy due to electron-electron interactions.
 - Potential energy due to electron-nucleus interactions.

Hohenberg Kohn Theory

- We cannot have two different systems with the same Ground State density.
- The ground state density is a unique function of the nuclei distribution. It is one-to-one relationship.

$$V_{ext} = -\sum_{i=1}^{N} \sum_{k=1}^{N_0} \frac{Ze^2}{4\pi\epsilon_0(r_i - r_k)}$$

- The electrons will be distributed according to the nuclei distribution.
- The ground state density is related to the minimum energy of the system.

Kohn-Sham Scheme

The potential energy

$$V_{\rm s} = V_{ext} + V_{ee}$$

$$V_{\rm s} = V_{ext}[n(r)] + \int \frac{e^2 n(r) d^3 r}{4\pi\epsilon_0 |r - r'|} + V_{xc}[n(r)]$$

Schrodinger equation

$$(-\frac{\hbar^2}{2m}\nabla^2 + V_s)\psi(r) = E\psi(r)$$

• The ground state density

$$n(r) = |\psi|^2$$

The ground state is related to minimum energy

Functional: function of a function

Kohn-Sham Scheme

Guess an initial density $n(r) = n^{in}(r)$

$$V_{\rm s} = V_{ext}[n(r)] + \int \frac{e^2 n(r) d^3 r}{4\pi\epsilon_0 |r - r'|} + V_{xc}[n(r)]$$

• Solve Schrodinger equation for ψ and E.

$$(-\frac{\hbar^2}{2m}\nabla^2 + V_s)\psi(r) = E\psi(r)$$

Calculate the density state Is it ground state?

$$n(r) = |\psi|^2$$

The ground state is related to minimum energy

Functional: function of a function
